Detailed Solution Plan

The proposed system consists of wearable sensors, a data processing unit, and an AI model.

First, wearable sensors attached to the astronaut collect real-time health data such as heart rate, oxygen saturation, and temperature.

Second, the collected data is sent to a central system where it is processed and analyzed.

The AI model uses machine learning techniques, specifically classification algorithms, to identify whether the astronaut's health is normal or abnormal. The model is trained using historical health data.

If the system detects unusual patterns, it immediately sends an alert to both the astronaut and mission control.

The system also stores data for long-term analysis, helping improve predictions over time.

This AI solution is scalable and can be adapted for different missions and environments.
